

Each of the $S \times S$ cells predicts B boxes, each with a confidence, and one set of C class probabilities. Their product, thresholded and de-duplicated with non-maximum suppression, gives the detections. The output tensor is $S \times S \times (5B + C)$: $7 \times 7 \times 30$ for $S = 7$, $B = 2$, $C = 20$.
